#### Commercial Members: Managed Care (HMO and POS), PPO, and Indemnity

#### TYPE 1 DIABETES

**Continuous glucose monitoring (CGM)** of glucose levels in interstitial fluid as a technique of diabetic monitoring may be considered **MEDICALLY NECESSARY** when the following situations occur:

- Patients with type 1 diabetes who have demonstrated an understanding of the technology, are motivated to use the device correctly and consistently, are expected to adhere to a comprehensive diabetes treatment plan supervised by a qualified provider, and are capable of using the device to recognize alerts and alarms; **or**
- Patients with type I diabetes who have recurrent, unexplained, severe-(generally blood glucose levels <50 mg/dl) hypoglycemia or impaired awareness of hypoglycemia that puts the patient or others at risk; **or**
- Patients with poorly controlled type I diabetes who are pregnant. Poorly controlled type 1 diabetes includes unexplained hypoglycemic episodes, hypoglycemic unawareness, suspected postprandial hyperglycemia, and recurrent diabetic ketoacidosis.

Use of an **automated insulin delivery system (artificial pancreas device system) with a low-glucose suspend feature** may be considered **MEDICALLY NECESSARY** if Food and Drug Administration–approved, in patients with type 1 diabetes who meet all of the following criteria:

- Age 6 and older, **AND**

- Patients with recurrent, unexplained, severe, (generally blood glucose levels less than 50 mg/dl) hypoglycemia for whom hypoglycemia puts the patient or others at risk, **OR**
- Patients who become pregnant whose diabetes is poorly controlled.

Use of an **automated insulin delivery system (artificial pancreas device system) designated as hybrid closed-loop insulin delivery system (with low glucose suspend and suspend before low features)** may be considered **MEDICALLY NECESSARY** if Food and Drug Administration–approved, in patients with type 1 diabetes who meet all of the following criteria:

- Age 6 and older, **AND**
- Patients with recurrent, unexplained, severe, (generally blood glucose levels less than 50 mg/dl) hypoglycemia for whom hypoglycemia puts the patient or others at risk, **OR**
- Patients who become pregnant whose diabetes is poorly controlled.

All other uses of monitoring of glucose levels and automated insulin delivery systems in interstitial fluid as a technique of diabetic monitoring for type 1 diabetes are considered **INVESTIGATIONAL**.

## **TYPE 2 DIABETES**

**CGM monitoring (including implantable CGM devices)** of glucose levels in interstitial fluid may be considered **MEDICALLY NECESSARY** in patients with type 2 diabetes who are willing and able to use the device, have adequate medical supervision AND who experience significant hypoglycemia on multiple daily doses of insulin or an insulin pump in the setting of insulin deficiency. Significant hypoglycemia may include recurrent, unexplained, severe (generally blood glucose levels <50 mg/dL) hypoglycemia or impaired awareness of hypoglycemia that puts the patient or others at risk.

Use of an **automated insulin delivery system (artificial pancreas device system) with a low-glucose suspend feature** may be considered **MEDICALLY NECESSARY** if Food and Drug Administration–approved, in patients with type 2 diabetes who meet all of the following criteria:

- Age 6 and older, **AND**
- Meets criteria for external insulin pump ([see medical policy #332 Insulin Delivery Devices](#)), **AND**
- Meets above criteria for long-term CGM monitoring.

Use of an **automated insulin delivery system (artificial pancreas device system) designated as hybrid closed-loop insulin delivery system (with low glucose suspend and suspend before low features)** may be considered **MEDICALLY NECESSARY** if Food and Drug Administration–approved, in patients with type 2 diabetes who meet all of the following criteria:

- Age 6 and older, **AND**
- Meets criteria for external insulin pump ([see medical policy #332 Insulin Delivery Devices](#)), **AND**
- Meets above criteria for long-term CGM monitoring.

All other uses of CGM monitoring of glucose levels and automated insulin delivery systems in interstitial fluid as a technique of diabetic monitoring for type 2 diabetes are considered **INVESTIGATIONAL**.

**Automated insulin delivery systems (artificial pancreas device system) with a low-glucose suspend feature** are considered **INVESTIGATIONAL** in patients with type 2 diabetes.

**Automated insulin delivery systems (artificial pancreas device system) designated as hybrid closed-loop insulin delivery systems (with low glucose suspend and suspend before low features)** are considered **INVESTIGATIONAL** in patients with type 2 diabetes.

All other uses of CGM monitoring of glucose levels and automated insulin delivery systems in interstitial fluid as a technique of diabetic monitoring for type 2 diabetes are considered **INVESTIGATIONAL**.

## GESTATIONAL DIABETES

**CGM device monitoring** of glucose levels in interstitial fluid in patients with gestational diabetes is considered **INVESTIGATIONAL**.

**Automated insulin delivery systems (artificial pancreas device system) with a low-glucose suspend feature and Automated insulin delivery systems (artificial pancreas device system)** designated as hybrid closed-loop insulin delivery systems (with low glucose suspend and suspend before low features) are considered **INVESTIGATIONAL** in patients with gestational diabetes.

### Medicare HMO Blue<sup>SM</sup> and Medicare PPO Blue<sup>SM</sup> Members

Medical necessity criteria and coding guidance for **Medicare Advantage members living in Massachusetts** can be found through the link below.

[Local Coverage Determinations \(LCDs\) for National Government Services, Inc.](#)

Local Coverage Determination (LCD): Glucose Monitors (L33822)

**Note:** To review the specific LCD, please remember to click “accept” on the CMS licensing agreement at the bottom of the CMS webpage.

For medical necessity criteria and coding guidance for **Medicare Advantage members living outside of Massachusetts**, please see the Centers for Medicare and Medicaid Services website at <https://www.cms.gov> for information regarding your specific jurisdiction.

### Prior Authorization Information

#### Inpatient

- For services described in this policy, precertification/preauthorization **IS REQUIRED** for all products if the procedure is performed **inpatient**.

#### Outpatient

- For services described in this policy, see below for products where prior authorization **might be required** if the procedure is performed **outpatient**.

|  | <b>Outpatient</b>                           |
|--|---|
| <b>Commercial Managed Care (HMO and POS)</b> | Prior authorization <b>is required.*</b>    |
| <b>Commercial PPO and Indemnity</b>          | Prior authorization is <b>not required.</b> |
| <b>Medicare HMO Blue<sup>SM</sup></b>        | Prior authorization <b>is required. *</b>   |
| <b>Medicare PPO Blue<sup>SM</sup></b>        | Prior authorization is <b>not required.</b> |

Annual re-authorization requests:

Prior authorization is required on an annual basis. If the patient met prior authorization requirements on initial approval, continued approval will be granted so long as the requesting provider deems the device clinically appropriate.

\*Prior Authorization Request Form: Continuous or Intermittent Monitoring of Glucose in Interstitial Fluid and Artificial Pancreas Device Systems

This form must be completed and faxed to: Medical and Surgical: 1-888-282-0780; Medicare Advantage: 1-800-447-2994.

[Click here for Continuous or Intermittent Monitoring of Glucose in Interstitial Fluid and Artificial Pancreas Device Systems Prior Authorization Request Form, #845.](#)

## CPT Codes / HCPCS Codes / ICD Codes

*Inclusion or exclusion of a code does not constitute or imply member coverage or provider reimbursement. Please refer to the member's contract benefits in effect at the time of service to determine coverage or non-coverage as it applies to an individual member.*

*Providers should report all services using the most up-to-date industry-standard procedure, revenue, and diagnosis codes, including modifiers where applicable.*

*The following codes are included below for informational purposes only; this is not an all-inclusive list.*

### For members with a pharmacy benefit:

A9276: Sensor; invasive (e.g., subcutaneous), disposable, for use with interstitial continuous glucose monitoring system, one unit=1-day supply

**Note:** If a member does not have a pharmacy benefit, the above noted item would be covered according to the member's benefit and certificate language.

**The above medical necessity criteria MUST be met for the following codes to be covered for Commercial Members: Managed Care (HMO and POS), PPO, Indemnity, and Medicare HMO Blue and Medicare PPO Blue:**

The following HCPCS codes **require prior authorization for Commercial HMO/POS and Medicare Advantage HMO Blue.**

### HCPCS Codes:

| HCPCS codes: | Code Description  |
|--------------|---|
| A9277        | Transmitter; external, for use with interstitial continuous glucose monitoring system   |
| K0553        | Supply allowance for therapeutic continuous glucose monitor (CGM) system, includes all supplies and accessories, 1-month supply = 1 unit of service |
| S1036        | Transmitter; external, for use with artificial pancreas device system   |

The following CPT and HCPCS codes **do not require prior authorization.**

### CPT Codes:

| CPT codes: | Code Description  |
|------------|---|
| 95249      | Ambulatory continuous glucose monitoring of interstitial tissue fluid via a subcutaneous sensor for a minimum of 72 hours; patient-provided equipment, sensor placement, hook-up, calibration of monitor, patient training, and printout of recording |
| 95250      | Ambulatory continuous glucose monitoring of interstitial tissue fluid via a subcutaneous sensor for a minimum of 72 hours; hook-up, calibration of monitor, patient training, removal of sensor, and printout of recording                            |
| 95251      | Ambulatory continuous glucose monitoring of interstitial tissue fluid via a subcutaneous sensor for a minimum of 72 hours; interpretation and report  |
| 0446T      | Creation of subcutaneous pocket with insertion of implantable interstitial glucose sensor, including system activation and patient training   |

### HCPCS Codes:

| HCPCS codes | Code Description   |
|-------------|--|
| A9276       | Sensor; invasive (e.g., subcutaneous), disposable, for use with interstitial continuous glucose monitoring system, 1 unit=1-day supply |
| A9278       | Receiver (monitor); external, for use with interstitial continuous glucose monitoring system   |
| E0784       | External ambulatory infusion pump, insulin   |

|       |   |
|-------|---|
| K0554 | Receiver (monitor), dedicated, for use with therapeutic continuous glucose monitor system |
|-------|---|

The above **medical necessity criteria MUST** be met for the following codes to be covered for Commercial Members: Managed Care (HMO and POS), PPO, Indemnity, Medicare HMO Blue and Medicare PPO Blue:

### HCPCS Codes:

| HCPCS codes | Code Description  |
|-------------|---|
| S1034       | Artificial pancreas device system (eg, low glucose suspend [LGS] feature) including continuous glucose monitor, blood glucose device, insulin pump and computer algorithm that communicates with all of the devices |
| S1035       | Sensor; invasive (eg, subcutaneous), disposable, for use with <b>artificial pancreas</b> device system, 1 unit = 1-day supply   |
| S1037       | Receiver (monitor); external, for use with <b>artificial pancreas</b> device system   |

The following ICD Diagnosis Codes are considered medically necessary when submitted with the HCPCS codes above if **medical necessity criteria** are met:

### ICD-10 Diagnosis Codes

| ICD-10-CM diagnosis codes: | Code Description   |
|----------------------------|--|
| E10.10                     | Type 1 Diabetes Mellitus with Ketoacidosis Without Coma                              |
| E10.11                     | Type 1 Diabetes Mellitus with Ketoacidosis with Coma                                 |
| E10.21                     | Type 1 Diabetes Mellitus with Diabetic Nephropathy                                   |
| E10.22                     | Type 1 Diabetes Mellitus with Diabetic Chronic Kidney Disease                        |
| E10.29                     | Type 1 Diabetes Mellitus with Other Diabetic Kidney Complication                     |
| E10.311                    | Type 1 Diabetes Mellitus with Unspecified Diabetic Retinopathy with Macular Edema    |
| E10.319                    | Type 1 Diabetes Mellitus with Unspecified Diabetic Retinopathy Without Macular Edema |
| E10.36                     | Type 1 Diabetes Mellitus with Diabetic Cataract                                      |
| E10.39                     | Type 1 Diabetes Mellitus with Other Diabetic Ophthalmic Complication                 |
| E10.40                     | Type 1 Diabetes Mellitus with Diabetic Neuropathy, Unspecified                       |
| E10.41                     | Type 1 Diabetes Mellitus with Diabetic Mononeuropathy                                |
| E10.42                     | Type 1 Diabetes Mellitus with Diabetic Polyneuropathy                                |
| E10.43                     | Type 1 Diabetes Mellitus with Diabetic Autonomic (Poly)Neuropathy                    |
| E10.44                     | Type 1 Diabetes Mellitus with Diabetic Amyotrophy                                    |
| E10.49                     | Type 1 Diabetes Mellitus with Other Diabetic Neurological Complication               |
| E10.51                     | Type 1 Diabetes Mellitus with Diabetic Peripheral Angiopathy Without Gangrene        |
| E10.52                     | Type 1 Diabetes Mellitus with Diabetic Peripheral Angiopathy With Gangrene           |
| E10.59                     | Type 1 Diabetes Mellitus with Other Circulatory Complications                        |

Local Coverage Determination (LCD): Glucose Monitors (L33822)

## Description

### **ARTIFICIAL PANCREAS DEVICE SYSTEMS**

#### **Diabetes and Glycemic Control**

Tight glucose control in patients with diabetes has been associated with improved health outcomes. The American Diabetes Association has recommended a glycosylated hemoglobin level below 7% for most patients. However, hypoglycemia, may place a limit on the ability to achieve tighter glycemic control. Hypoglycemic events in adults range from mild to severe based on a number of factors including the glucose nadir, the presence of symptoms, and whether the episode can be self-treated or requires help for recovery. Children and adolescents represent a population of type 1 diabetics who have challenges in controlling hyperglycemia and avoiding hypoglycemia. Hypoglycemia is the most common acute complication of type 1 diabetes.

Table 1 is a summary of selected clinical outcomes in type 1 diabetes clinical management and research.

**Table 1. Outcome Measures for Type 1 Diabetes**

| Measure  | Definition   | Guideline type  | Organization                                  | Date |
|--|--|---|---|------|
| <b>Hypoglycemia</b>                            |  | Stakeholder survey, expert opinion with evidence review           | Type 1 Diabetes Outcome Program <sup>a1</sup> | 2017 |
| Level 1  | Glucose <70mg/dl but ≥ 54 mg/dl  |   |   |      |
| Level 2  | Glucose <54 mg/dl  |   |   |      |
| Level 3  | Event characterized by altered mental/physical status requiring assistance |   |   |      |
| <b>Hypoglycemia</b>                            | Same as Type 1 Diabetes Outcome Program <sup>a</sup>                       | Professional Practice Committee with systematic literature review | ADA <sup>2</sup>                              | 2019 |
| <b>Hypoglycemia</b>                            |  | Clinical Practice Consensus                                       | ISPAD <sup>3</sup>                            | 2018 |
| Clinical alert for evaluation and/or treatment | Glucose <70mg/dl   |   |   |      |
| Clinically important or serious                | Glucose <54 mg/dl  |   |   |      |

|                             |   |  |   |      |
|-----------------------------|---|--|---|------|
| Severe hypoglycemia         | Severe cognitive impairment requiring external assistance by another person to take corrective action |  |   |      |
| <b>Hyperglycemia</b>        |   |  | Type 1 Diabetes Outcome Program <sup>a1</sup> | 2017 |
| Level 1                     | Glucose >180 mg/dL and ≤250 mg/dL   |  |   |      |
| Level 2                     | Glucose >250 mg/dL  |  |   |      |
| Time in Range <sup>b</sup>  | Percentage of glucose readings in the range of 70–180 mg/dL per unit of time                          |  | Type 1 Diabetes Outcome Program <sup>a</sup>  | 2017 |
| Diabetic ketoacidosis (DKA) | Elevated serum or urine ketones > ULN<br>Serum bicarbonate <15 mEq/L<br>Blood pH <7.3                 |  | Type 1 Diabetes Outcome Program <sup>a3</sup> | 2017 |

ADA: American Diabetes Association, ISPAD: International Society for Pediatric and Adolescent Diabetes; ULN: upper limit of normal.

<sup>a</sup>Steering Committee: representatives from American Association of Clinical Endocrinologists (AACE), American Association Diabetes Educators, the American Diabetes Association (ADA), the Endocrine Society, JDRF International, The Leona M. and Harry B. Helmsley Charitable Trust, the Pediatric Endocrine Society, type 1 diabetes Exchange.

<sup>b</sup>Time in range: has also been adopted by researchers evaluating the precision and effectiveness of emerging glucose monitoring and automated insulin delivery technologies.

### Treatment

Type 1 diabetes is caused by the destruction of the pancreatic beta cells which produce insulin, and the necessary mainstay of treatment is insulin injections. Multiple studies have shown that intensive insulin treatment, aimed at tightly controlling blood glucose, reduces the risk of long-term complications of diabetes, such as retinopathy and renal disease. Optimal glycemic control, as assessed by glycated hemoglobin, and avoidance of hyper- and hypoglycemic excursions have been shown to prevent diabetes-related complications. Currently, insulin treatment strategies include either multiple daily insulin injections or continuous subcutaneous insulin infusion with an insulin pump.

The use of the continuous glucose monitoring component of diabetes self-management is specifically addressed in evidence review 1.01.20.

Restoration of pancreatic function is potentially available through islet cell or allogeneic pancreas transplantation. Evidence reviews of these interventions are in policy #[324](#) and policy #[328](#) respectively.

### **CONTINUOUS OR INTERMITTENT MONITORING OF GLUCOSE IN INTERSTITIAL FLUID**

#### **Blood Glucose Control**

The advent of blood glucose monitors for use by patients in the home revolutionized the management of diabetes. Using fingersticks, patients can monitor their blood glucose levels both to determine the adequacy of hyperglycemia control and to evaluate hypoglycemic episodes. Tight glucose control, defined as a strategy involving frequent glucose checks and a target hemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) level in the range of 7%, is now considered the standard of care for diabetic patients. Randomized controlled trials assessing tight control have demonstrated benefits for patients with type 1 diabetes in decreasing microvascular complications. The impact of tight control on type 1 diabetes and macrovascular complications such as stroke or myocardial infarction is less certain. The Diabetes Control and

Complications Trial (2002) demonstrated that a relative HbA<sub>1c</sub> level reduction of 10% is clinically meaningful and corresponds to approximately a 40% decrease in risk for progression of diabetic retinopathy and 25% decrease in risk for progression of renal disease.<sup>1</sup>

Due to an increase in turnover of red blood cells during pregnancy, HbA<sub>1c</sub> levels are slightly lower in women with a normal pregnancy compared with nonpregnant women. The target A<sub>1c</sub> in women with diabetes is also lower in pregnancy. The American Diabetes Association recommends that, if achievable without significant hypoglycemia, the A<sub>1c</sub> levels should range between 6.0% to 6.5%; an A<sub>1c</sub> level less than 6% may be optimal as the pregnancy progresses.<sup>2</sup>

Tight glucose control requires multiple daily measurements of blood glucose (ie, before meals and at bedtime), a commitment that some patients may find difficult to meet. The goal of tight glucose control has to be balanced with an associated risk of hypoglycemia. Hypoglycemia is known to be a risk in patients with type 1 diabetes. While patients with insulin-treated type 2 diabetes may also experience severe hypoglycemic episodes, there is a lower relative likelihood of severe hypoglycemia compared with patients who had type 1 diabetes.<sup>3,4</sup> An additional limitation of periodic self-measurements of blood glucose is that glucose levels are seen in isolation, and trends in glucose levels are undetected. For example, while a diabetic patient's fasting blood glucose level might be within normal values, hyperglycemia might be undetected postprandially, leading to elevated HbA<sub>1c</sub> levels.

### **Management**

Recently, measurements of glucose in the interstitial fluid have been developed as a technique to measure glucose values automatically throughout the day, producing data that show the trends in glucose levels. Although devices measure glucose in the interstitial fluid on a periodic rather than a continuous basis, this type of monitoring is referred to as continuous glucose monitoring (CGM).

Currently, CGM devices are of two designs; real-time CGM (rtCGM) provide real-time data on glucose level, glucose trends, direction, and rate of change and, intermittently viewed (iCGM) devices that show continuous glucose measurements retrospectively. These devices are also known as flash-glucose monitors (FGM).

Approved devices now include devices indicated for pediatric use and those with more advanced software, more frequent measurements of glucose levels, or more sophisticated alarm systems. Devices initially measured interstitial glucose every 5 to 10 minutes and stored data for download and retrospective evaluation by a clinician. With currently available devices, the intervals at which interstitial glucose is measured ranges from every 1-2 minutes to 5 minutes, and most provide measurements in real-time directly to patients. While CGM potentially eliminates or decreases the number of required daily fingersticks, it should be noted that, according to the Food and Drug Administration labeling, some marketed monitors are not intended as an alternative to traditional self-monitoring of blood glucose levels but rather as adjuncts to monitoring, supplying additional information on glucose trends not available from self-monitoring. Also, devices may be used intermittently (i.e., for periods of 72 hours) or continuously (i.e., on a long-term basis).

### **Summary**

#### **ARTIFICIAL PANCREAS**

Automated insulin delivery systems, also known as artificial pancreas device systems, link a glucose monitor to an insulin infusion pump that automatically takes action (eg, suspends or adjusts insulin infusion) based on the glucose monitor reading. These devices are proposed to improve glycemic control in patients with insulin-dependent diabetes, in particular, reduction of nocturnal hypoglycemia.

The following conclusions are based on a review of the evidence, including but not limited to, published evidence and clinical expert opinion, solicited via BCBSA's Clinical Input Process.

For individuals who have type 1 diabetes who receive an artificial pancreas device system with a low-glucose suspend feature, the evidence includes two randomized controlled trials (RCTs) conducted in home settings. Relevant outcomes are symptoms, change in disease status, morbid events, resource

utilization, and treatment-related morbidity. Primary eligibility criteria of the key RCT, the Automation to Simulate Pancreatic Insulin Response (ASPIRE) trial, were ages 16-to-70 years old, type 1 diabetes, glycosylated hemoglobin levels between 5.8% and 10.0%, and at least 2 nocturnal hypoglycemic events ( $\leq 65$  mg/dL) lasting more than 20 minutes during a 2-week run-in phase. Both trials required at least six months of insulin pump use. Both RCTs reported significantly less hypoglycemia in the treatment group than in the control group. In both trials, primary outcomes were favorable for the group using an artificial pancreas system; however, findings from one trial were limited by nonstandard reporting of hypoglycemic episodes, and findings from the other trial were no longer statistically significant when two outliers (children) were excluded from analysis. The RCT limited to adults showed an improvement in the primary outcome (area under the curve for nocturnal hypoglycemic events). The area under the curve is not used for assessment in clinical practice but the current technology does allow user and provider review of similar trend data with continuous glucose monitoring. Results from the ASPIRE study suggested that there were increased risks of hyperglycemia and potential diabetic ketoacidosis in subjects using the threshold suspend feature. This finding may be related to whether or not actions are taken by the user to assess glycemic status, etiology of the low glucose (activity, diet or medication) and to resume insulin infusion. Both retrospective and prospective observational studies have reported reductions in rates and severity of hypoglycemic episodes in automated insulin delivery system users. The evidence is sufficient that the magnitude of reduction for hypoglycemic events in the type 1 diabetes population is likely to be clinically significant. Limitations of the published evidence preclude determining the effects of the technology on overall glycemic control as assessed by hemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) and other parameters and thus, net health outcomes. Evidence reported through clinical input supports that the outcome of hypoglycemia prevention provides a clinically meaningful improvement in net health outcome, and this use is consistent with generally accepted medical practice. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have type 1 diabetes who receive an artificial pancreas device system with a hybrid closed-loop insulin delivery system, the evidence includes multicenter pivotal trials using devices cleared by the U.S. Food and Drug Administration, supplemental data and analysis for expanded indications and more recent studies focused on children and adolescents. Three crossover RCTs using a similar first-generation device approved outside the United States have been reported. Relevant outcomes are symptoms, change in disease status, morbid events, resource utilization, and treatment-related morbidity. Of the three crossover RCTs assessing a related device conducted outside the United States, two found significantly better outcomes (ie, time spent in nocturnal hypoglycemia and time spent in preferred glycemic range) with the device than with standard care and the other had mixed findings (significant difference in time spent in nocturnal hypoglycemia and no significant difference in time spent in preferred glycemic range). For the U.S. regulatory registration pivotal trial, the primary outcomes were safety and not efficacy. Additional evidence from device performance studies and clinical studies all demonstrate reductions in time spent in various levels of hypoglycemia, improved time in range (70-180 mg/dl), rare diabetic ketoacidosis and few device-related adverse events. The evidence is sufficient that the magnitude of reduction for hypoglycemic events in the type 1 diabetes population is likely to be clinically significant. The variations in the definition of primary and secondary outcomes in the study design and conduct of the published evidence are limitations that preclude determining the effects of the technology on net health outcomes. Evidence reported through clinical input supports that the use of hybrid closed loop artificial pancreas device systems provides a clinically meaningful improvement in net health outcome and is consistent with generally accepted medical practice. Reduction in the experience of hypoglycemia and inappropriate awareness of hypoglycemia and glycemic excursions were identified as important acute clinical outcomes in children, adolescents, and adults and are related to the future risk for end-organ complications. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

### **CONTINUOUS OR INTERMITTENT MONITORING OF GLUCOSE IN INTERSTITIAL FLUID**

Tight glucose control in patients with diabetes has been associated with improved health outcomes. Several devices are available to measure glucose levels automatically and frequently (e.g., every 5-10 minutes). The devices measure glucose in the interstitial fluid and are approved as adjuncts to or replacements for traditional self-monitoring of blood glucose levels. Devices can be used on a long-term (continuous) or short-term (often referred to as intermittent) basis.

The following conclusions are based on a review of the evidence, including but not limited to, published evidence and clinical expert opinion, solicited via BCBSA's Clinical Input Process.

### **Type 1 Diabetes**

For individuals with type 1 diabetes who are willing and able to use the device, and have adequate medical supervision, who receive long-term (continuous) glucose monitoring (CGM), the evidence includes randomized controlled trials (RCTs) and systematic reviews. Relevant outcomes are symptoms, morbid events, quality of life (QOL), and treatment-related morbidity. Systematic reviews have generally found that at least in the short-term, long-term CGM resulted in significantly improved glycemic control for adults and children with type 1 diabetes, particularly highly compliant patients. A 2017 individual patient data analysis, pooling data from 11 RCTs, found that reductions in hemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) levels were significantly greater with real-time CGM than with a control intervention. Two RCTs in patients who used multiple daily insulin injections and were highly compliant with CGM devices during run-in phases found that CGM was associated with a larger reduction in HbA<sub>1c</sub> levels than previous studies. One of the two RCTs prespecified hypoglycemia-related outcomes and reported that time spent in hypoglycemia was significantly less in the CGM group. One RCT in pregnant women with type 1 diabetes, which compared real-time CGM with self-monitoring of blood glucose, has also reported a difference in change in HbA<sub>1c</sub> levels, an increased percentage of time in the recommended glucose control target range, a smaller proportion of infants who were large for gestational age, a smaller proportion of infants who had neonatal intensive care admissions lasting more than 24 hours, a smaller proportion of infants who had neonatal hypoglycemia requiring treatment, and reduced total hospital length of stay all favoring CGM. The evidence is sufficient that the long-term use of CGM provides an improvement in net health outcomes for persons with type 1 diabetes mellitus.

For individuals with type 1 diabetes who have poor control of diabetes despite the use of best practices or when basal insulin levels need to be determined prior to insulin pump initiation who receive short-term glucose monitoring, the evidence includes RCTs and systematic reviews. The relevant outcomes are symptoms, morbid events, QOL, and treatment-related morbidity as well as intermediate outcomes related to measures of glucose control such as frequency and time in hypoglycemia and hyperglycemia. The evidence for short-term monitoring on glycemic control is mixed, and there was no consistent in HbA<sub>1c</sub> levels. Some trials have reported improvements in glucose control for the intermittent monitoring group but limitations in this body of evidence preclude conclusions. The definitions of control with short-term CGM use, duration of use and the specific monitoring protocols varied. In some studies, short-term monitoring was part of a larger strategy aimed at optimizing glucose control, and the impact of monitoring cannot be separated from the impact of other interventions. Studies have not shown an advantage for intermittent glucose monitoring in reducing severe hypoglycemia events, but the number of events reported is generally small and effect estimates imprecise. The limited duration of use may preclude an assessment of any therapeutic effect. Two RCTs of short-term CGM use for monitoring in pregnancy included women with both type 1 and 2 diabetes, with most having type 1 diabetes. One trial reported a difference in HbA<sub>1c</sub> levels at 36 weeks; the proportion of infants that were large for gestational age (>90th percentile) favored CGM while the second trial did not. The differences in the proportions of infants born via cesarean section, gestational age at delivery, and infants with severe hypoglycemia were not statistically significant in either study. Limitations of the published evidence preclude determining the effects of the technology on net health outcome. Evidence reported through clinical input supports that this use provides a clinically meaningful improvement in net health outcome and is consistent with generally accepted medical practice when used in specific situations such as poor control of diabetes despite the use of best practices or when basal insulin levels need to be determined prior to insulin pump initiation. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

### **Type 2 Diabetes**

For individuals with type 2 diabetes who receive long-term CGM, the evidence includes RCTs. The relevant outcomes are symptoms, morbid events, QOL, and treatment-related morbidity. Most RCTs of CGM in patients with type 2 trials found statistically significant benefits of CGM regarding glycemic control. However, the degree of HbA<sub>1c</sub> reduction and the difference in HbA<sub>1c</sub> reduction between groups

might not be clinically significant. Moreover, additional evidence would be needed to show what levels of improvements in HbA1c levels over the short-term would be linked to meaningful improvements over the long-term in health outcomes such as diabetes-related morbidity and complications. Also, the variability in entry criteria as well as among interventions makes it difficult to identify an optimal approach to CGM use; the studies used a combination of intermittent and continuous monitoring with a review of data in real-time or at study visits only. Only the DIAMOND RCT (n=158) has used real-time CGM in type 2 diabetes. Selected patients were highly compliant during a run-in phase. The difference in change in HbA1c levels from baseline to 24 weeks was -0.3% favoring CGM. The difference in the proportion of patients with a relative reduction in HbA1c level by 10% or more was 22% favoring CGM. There were no differences in the proportions of patients with an HbA1c level of less than 7% at week 24. There were no events of severe hypoglycemia or diabetic ketoacidosis in either group. The treatment groups did not differ in any of the QOL measures. RCTs using flash glucose-sensing technology as a replacement for self-monitoring of blood glucose for the management of insulin-dependent treated type 2 diabetes found no difference in HbA1c change at 6 and 12 months between groups. However, time in severe hypoglycemia (<45mg/dL) was reduced for intervention participants. Two trials of CGM have enrolled pregnant women with type 2 diabetes, but the total number of women with type 2 diabetes included in both trials is only 58. One study reported a difference in HbA1c levels at 36 weeks, and the proportion of infants that were large for gestational age (>90th percentile) favored CGM while the second study did not. Neither trial reported analyses stratified by diabetes type. Limitations of the published evidence preclude determining the effects of the technology on net health outcome. Evidence reported through clinical input for long-term (continuous) CGM in patients with type 2 diabetes who do not require insulin did not provide strong support of a safety benefit and clinically meaningful improvement in net health outcome. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals with type 2 diabetes who are willing and able to use the device and have adequate medical supervision and who experience significant hypoglycemia on multiple daily doses of insulin or an insulin pump in the setting of insulin deficiency who receive long-term (continuous) glucose monitoring, the evidence includes a systematic review and non-randomized study with 12-month follow-up. The relevant outcomes are the frequency of and time spent in hypoglycemia, the incidence of hypoglycemic episodes, complications of hypoglycemia, and QOL. The available studies demonstrate that CGM can significantly reduce time in hypoglycemia and frequency of hypoglycemia events both during the day and at night. At 12-month follow-up, hypoglycemic events were reduced by 40.8% to 61.7% with a greater relative reduction in the most severe thresholds of hypoglycemia. The published evidence supports a meaningful improvement in the net health outcome. Evidence reported through clinical input provides additional clinical context and based on both the published evidence and clinical input the following patient selection criteria are associated with a clinically meaningful improvement in net health outcome and are consistent with generally accepted medical practice: selected patients with type 2 diabetes who are (1) willing and able to use the CGM device and have adequate medical supervision and (2) experiencing significant hypoglycemia on multiple daily doses of insulin or an insulin pump in the setting of insulin deficiency. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals with type 2 diabetes who require multiple daily doses of insulin and have poor control of diabetes despite the use of best practices or when basal insulin levels need to be determined prior to insulin pump initiation who receive short-term CGM monitoring, the evidence includes RCTs and systematic reviews. The relevant outcomes are symptoms, morbid events, QOL, and treatment-related morbidity. Systematic reviews of three to four RCTs have found statistically significant benefits from CGM regarding glycemic control. However, the degree of HbA1c reduction and the difference in HbA1c reductions between groups may not be clinically significant. Also, the limited number of RCTs and variability among interventions make it difficult to identify an optimal approach to CGM or a subgroup of type 2 diabetes patients who might benefit. Moreover, studies of CGM in patients with type 2 diabetes have generally not addressed the clinically important issues of severe hypoglycemia and diabetic complications. Very few pregnant women with type 2 diabetes have been included in RCTs. Limitations of the published evidence preclude determining the effects of the technology on net health outcome. Evidence reported through clinical input for use of short-term CGM in patients with type 2 diabetes who require multiple daily doses of insulin supports that this use provides a clinically meaningful improvement

in net health outcome and is consistent with generally accepted medical practice when used in specific situations such as poor control of diabetes despite use of best practices or when basal insulin levels need to be determined prior to insulin pump initiation. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

### Gestational Diabetes

For individuals who are pregnant with gestational diabetes who receive long-term CGM or short-term (intermittent) glucose monitoring, the evidence includes an RCT. Relevant outcome are symptoms, morbid events, QOL, and treatment-related morbidity. In the RCT, the type of glucose monitoring was unclear. Trial reporting was incomplete; however, there was no difference between the groups for most reported outcomes. The evidence is insufficient to determine the effects of the technology on health outcomes.

Tight glucose control in patients with diabetes has been associated with improved health outcomes. Several devices are available to measure glucose levels automatically and frequently (e.g., every 5-10 minutes). The devices measure glucose in the interstitial fluid and are approved as adjuncts to or replacements for traditional self-monitoring of blood glucose levels. Devices can be used on an intermittent (short-term) basis or a continuous (long-term) basis.
